Final_Google_Stock Price

LSTM that predicts upwards and downwards trend of google stockprice Many layers with dropout regularisation to prevent overfitting

Part 1 - Data Preprocessing

[1]:
```
# Importing the libraries
import numpy as np #allow to make arrays
import matplotlib.pyplot as plt #visualize results on charts
import pandas as pd #import dataset and manage easily
```

Load the Training Dataset and Use the Open Stock Price Column to Train Your Model.

[2]:
```
# Importing the training set - only importing training set, test set later  on
#rnn has no idea of the test set's data, then after training is done, test set␣
↪will eb important
dataset_train = pd.read_csv(r'D:
↪\SRB_Backup\Deep_Learning\LP_V\SRB_Dataset\stock\Google_Stock_Price_Train.
↪csv')

#need to make into numpy arrays because only nump arrays can be input values in␣
↪keras
training_set = dataset_train.iloc[:, 1:2].values

#getting everything from the columns (.values makes the numpy array)
```

[3]:
```
training_set.shape
```

[3]: (1258, 1)

[4]:
```
# Feature Scaling
# Normalizing the Dataset
from sklearn.preprocessing import MinMaxScaler
sc = MinMaxScaler(feature_range = (0, 1))
training_set_scaled = sc.fit_transform(training_set)
#fit (gets min and max on data to apply formula) tranform(compute scale stock␣
↪prices to each formula)
```

Creating X_train and y_train Data Structures.

[5]:
```
# Creating a data structure with 60 timesteps and 1 output
#60 times steps- at each time t and look at 60 previous time steps, then make␣
↪new prediction
# 1 time step leads to overfitting, 20 is still too low
#60 previous financial days- in 3 months
X_train = []
y_train = []
for i in range(60, 1257): # upper bound is number of values
  X_train.append(training_set_scaled[i-60:i, 0]) #takes 60 previous stock␣
↪prices from 60 past stock prices
  y_train.append(training_set_scaled[i, 0]) #contains stock price learned to␣
↪predict
X_train, y_train = np.array(X_train), np.array(y_train) # make into numpy␣
↪arrays
#Need to add dimension to because not only prescition with one stock price but␣
↪other indicators
# (like other columns in dataset  or other stocks that may affect this one )
```

[6]:
```
# Reshaping- add dimension in numpy array
X_train = np.reshape(X_train, (X_train.shape[0], X_train.shape[1], 1))
#adds dimension in numpy array currently only have one indicator, with new␣
↪dimension will
# have more indicators, be compatible for "input shape" of RNN
# format according to keras documentation
```

[7]:
```
X_train.shape
```

[7]: (1197, 60, 1)

Part 2 - Building the RNN stacked lstm with dropout regularization to prevent overfitting

[8]:
```
# Importing the Keras libraries and packages
from keras.models import Sequential
from keras.layers import Dense
from keras.layers import LSTM
from keras.layers import Dropout
```

[9]:
```
# Initialising the RNN
regressor = Sequential()
#reps sequence of layers, predicting continous values (so it is a regression)
```

[10]:
```
# Adding the first LSTM layer and some Dropout regularisation
#dropout to prevent overfitting
regressor.add(LSTM(units = 50, return_sequences = True, input_shape = (X_train.
↪shape[1], 1)))
#regressor- object of sequential class, can add layers to networ.
#use lstm class and create object of lstm class- 3 args
```

```
#num of units, return sequences- set to true because is stacked lstms, and shape
#units- neurons in first layer. 50 in layers for high dimensionality, can␣
↪capture upward and downward
regressor.add(Dropout(0.2))
# takes arg of dropout late- num of neurons want to drop. dropping 20% of␣
↪neurons to be ignored
#during trianing for each iteration. 10 neurons will be dropped out
```

[11]:
```
# Adding a second LSTM layer and some Dropout regularisation
# total of 4 layers, simply need to copy, only change is input shape so dont␣
↪need to specify that,
#automatically recognised through input shape

regressor.add(LSTM(units = 50, return_sequences = True))

regressor.add(Dropout(0.2))
```

[12]:
```
# Adding a third LSTM layer and some Dropout regularisation
# same as second layer
regressor.add(LSTM(units = 50, return_sequences = True))
regressor.add(Dropout(0.2))
```

[13]:
```
# Adding a fourth LSTM layer and some Dropout regularisation
# almost same, but return sequence is false because it is the last lstm layer
#(so it is removed becasue default is false)
regressor.add(LSTM(units = 50))
regressor.add(Dropout(0.2))
```

[14]:
```
# Adding the output layer
#add fully connected layer through dense class- dimesion/units/neurons is 1
regressor.add(Dense(units = 1))
```

[15]:
```
# Compiling the RNN
#regressior because predicting continuous value,
regressor.compile(optimizer = 'adam', loss = 'mean_squared_error')
```

Fitting the Model.

[16]:
```
# Fitting the RNN to the Training set
#have not made connection to training set, training will take place
regressor.fit(X_train, y_train, epochs = 200, batch_size = 32)
#100 gives good convergence trained on certain batch sizes,
```
